None of these regimens offers any advantage over ceftriaxone and there is less clinical experience with them for the treatment of uncomplicated gonorrhea.

Disseminated gonococcal infection due to a β

The high frequency of pharyngeal gonorrhea with substantial underscreening and the increased understanding of wide individual pharmacokinetic and pharmacodynamic variability has contributed to the recommendation for the increased ceftriaxone dose. Disseminated Gonococcal Infection Complicated by Prosthetic Joint Infection: Case Report and Genomic and Phylogenetic Analysis

The presence of transformation sequences just downstream from the *gyrA* sequences suggests that transformation may play a role in the spread of *gyrA* mutations between gonococcal strains *in vivo*. Small, smooth, and non-pigmented colonies are produced after 18-24 hours of incubation.

Evidence and Rationale Antimicrobial stewardship. The observations underlying the current dogma likely come from physiological and anatomical differences in the male and female urogenital tracts, making neutrophil influx in men much more noticeable and easier to diagnose than infections in women.

Increasing concern for antimicrobial stewardship and the potential impact of dual therapy on commensal organisms and concurrent pathogens 3 , in conjunction with the continued low incidence of ceftriaxone resistance and the increased incidence of azithromycin resistance, has led to reevaluation of this recommendation.

Fluoroquinolone Resistance in *Neisseria gonorrhoeae*

Clinical manifestations in women are more likely to go unnoticed, as inflammation does not occur in the same niche as urination and thus is less likely to be painful.
