Carcinisation

In this paper we summarize the results of our recent studies into the evolution of the crab-like morphotype i. Phylogenies of Galatheoidea based on molecular + morphological A and morphological data B. This secondary loss of the features of a crab-like habitus has been termed decarcinization.

How do crustaceans become crabs?

The course of the descending artery and the position of its junction with the ventral vessel vary between the taxa.

One hundred years of carcinization

The paired neuropils of the first pleonal neuromere pn1 are close together medially and may be confluent with each other. Broad chelipeds and a reduction of the rostrum also contribute to a compact crab-like habitus, but were not investigated in this study. The neuropils of the pleonal neuromeres are closely spaced medially and in some species can actually be confluent with each other.

. Ascending arteries are indicated by asterisks. To answer the question of whether structural coherence exists between a crab-like habitus and internal morphology, the external features which characterize a crab-like habitus must first be defined precisely.
